What is a Sorting Function?
The sorting problem

Cormen, Leiserson and Rivest (1990):

“**Input:** A sequence of n numbers \( \langle a_1, \ldots, a_n \rangle \).

**Output:** A permutation (reordering) \( \langle a'_1, \ldots, a'_n \rangle \) of
the input sequence such that \( a'_1 \leq a'_2 \leq \ldots \leq a'_n \).’

The input sequence is usually an n-element array,
although it may be represented in some other fashion.

[...]

Knuth (1998):

“[Given records with keys \( k_1 \ldots k_N \).] The goal of
sorting is to determine a permutation \( p(1)p(2)\ldots p(N) \)
of the indices \( \{1, 2, \ldots, N\} \) that will put the keys into
nondecreasing order [.]”
Questions

- Can you only sort numbers? What about strings? Sets? Trees? Graphs?
- Is $\leq$ fixed by data type of elements?
- What kind of relation is $\leq$? Total order on elements, in particular antisymmetric?
- Permutation as output or just permuted output?
- ...
What is a sorting criterion?

**Sorting criterion: Total order?**

- A sorting algorithm permutes input sequences for a certain explicitly given or implicitly understood *sorting criterion*: its output elements have to be in some given “order”.
- What does it mean to be “in order”?

**Sorting criterion, first attempt:** A total order specification.
What is a sorting criterion?

**Sorting criterion: Key order?**

- Sorting algorithms operate on *records* and sort them according to their *keys*.
- E.g. addresses sorted according to their last names.
- More generally, records sorted according to a *key function*;
- E.g. words in dictionary sorted according to their *signature* (characters in ascending lexicographic order).
- Total order on the *key* domain, but *not* on the records!

**Definition (Key order)**

A *key order* for set $S$ is a pair consisting of a total order $(K, \leq_K)$, and a function $key : S \rightarrow K$.

**Sorting criterion, second attempt**: A key order specification.
What is a sorting criterion?

Key orders too concrete

- *Different* key orders may be *equivalent* for sorting purposes.
- E.g. sorting strings with the key function mapping all letters in a word to upper case, or another key function mapping all letters to lower case.
- Both key orders define the same *total preorder*
What is a sorting criterion?

**Sorting criterion: Total preorder!**

**Definition (Total preorder, order, ordering relation)**

An *total preorder (order)* $(S, R)$ is a set $S$ together with a binary relation $R \subseteq S \times S$ that is

- **transitive:**
  \[ \forall x, y, z \in S : (x, y) \in R \land (y, z) \in R \implies (x, z) \in R; \text{ and} \]

- **total:** \[ \forall x, y \in S : (x, y) \in R \lor (y, x) \in R \]

**Sorting criterion, definition:** A total preorder specification.

Fritz Henglein

DIKU, University of Copenhagen

What is a Sorting Function?
Properties of sorting algorithms

Permutation versus permuted input

Functionality of a sorting function:
- **Input**: A sequence of elements, e.g. `["foo", "bar", "foo"]`
- **Output**: A *permutation*, `[2, 3, 1]` or *permuted input elements*: `["bar", "foo", "foo"]`
- Not equivalent! Permutation provides more “intensional” information.

What if we are only interested in permuted elements?
Unnecessary burden on algorithms designer (“too concrete specification”) to have to return a permutation, not just the permuted elements. So:

**Property 1 (Permutativity)**: A sorting algorithm permutes its input: it transforms, possibly destructively, an input sequence into a rearranged sequence containing the same elements.
Imagine you have a sorting algorithm, but nobody has told you the ordering relation $\leq$ (the sorting criterion).

You are given two distinct input elements $x_1, x_2$.

Apply the sorting algorithm to $[x_1, x_2]$ and to $[x_2, x_1]$.

Assume in both cases the result is $[x_1, x_2]$.

What can you conclude about the ordering relation between $x_1$ and $x_2$?

- We know for sure: $x_1 \leq x_2$!
- But what about $x_2 \leq x_1$?
- We would like to conclude that $x_2 \not\leq x_1$. 
Locality

**Property 2 (locality):** A sorting algorithm can be used as a decision procedure for the order \((S, R)\) it sorts according to: Given \(x_1, x_2\) run it on \(x_1 x_2\) and on \(x_2 x_1\). If at least one of the results is \(x_1 x_2\) then \(R(x_1, x_2)\) holds; otherwise it does *not* hold.
Satellite data (keys and records)

Cormen, Leiserson, Rivest (1990):

“Each record contains a key, which is the value to be sorted [sic!], and the remainder of the record consists of satellite data, which are usually carried around with the key. In practice, when a sorting algorithm permutes the keys, it must permute the satellite data as well.”

Note: Satellite data may be empty.

**Property 3 (oblviousness):** A sorting algorithm only copies and moves satellite data without inspecting them.
A sorting algorithm may be stable

- For some applications it is important that equivalent input elements—e.g. records with the same key—are returned in the same order as in the input.
- Example: Individual sorting steps in least-significant-digit (LSD) radix sorting.
- So, a final property that some, but not all sorting algorithms have is *stability*.

**Property 4 (stability):** A stable sorting algorithm returns equivalent elements in the same relative order as they appear in the input.
A sorting algorithm:

1. operates on sequences and permutes them such that they obey a given total preorder;
2. decides the given ordering relation;
3. treats order-equivalent elements obliviously;
4. outputs order-equivalent elements in the same relative order as they occur in the input, if it is required to be stable.

All these properties can be formulated as extensional properties of the input/output behavior for a given total preorder.
That is not the question!

- Question is: What is a sorting function? (Period. No order given.)
- Why is this interesting?
  - Message at last WG2.8 meeting: Don’t use binary comparison function to provide access to ordering relation of an ordered type: algorithmic bottleneck!
  - Use $n$-ary sorting function (or variant, such as discriminator): no algorithmic bottleneck, no leaking of representation information.
  - But how do we know that the exposed function is a “sorting” function? We are not given an order to start with!
- General problem: We are used to defining sorting given an order. We now want to reverse this: define order given sorting function.
What makes a function $f$ a sorting function?
Let us formulate some intrinsic requirements: properties $f$ must have without reference to any \textit{a priori} order.

**Definition (Permutation function)**

A function $f$ is a \textit{permutation function} if $f : S^* \rightarrow S^*$ and $f(\vec{x})$ is a permutation of $\vec{x}$ for all $\vec{x} \in S$.

**Requirement 1:** $f$ must be a permutation function.
Definition (Consistency with ordering relation)

Let \( f : S^* \rightarrow S^* \) be a permutation function. We say \( f \) and ordering relation \( R \) on \( S \) are consistent with each other if for all \( y_1y_2 \ldots y_n = f(x_1x_2 \ldots x_n) \) we have \( R(y_i, y_{i+1}) \) for all \( 1 \leq \omega i < \omega n \).

**Requirement (turns out to be trivial):** \( f \) must be consistent with some ordering relation \( R \).
One permutation function, many ordering relations

- Each permutation function $f$ is consistent with many ordering relations, in particular the trivial one: $S \times S$.
- $S \times S$ is the the biggest (least informative) relation: it may relate $x_1, x_2$ even though $f$ never outputs them in that relative order.
- Does $f$ have a smallest (most informative) relation?
Definition (Canonically induced ordering relation)

Let $f : S^* \rightarrow S^*$ be a permutation function. We call $R$ the \textit{canonically induced ordering relation} of $f$ if

1. $f$ is consistent with $R$ and
2. for all $R'$ that $f$ is consistent with we have $R \subseteq R'$.

We write $\leq_f$ for $R$ and $\equiv_f$ for the equivalence relation induced by $\leq_f$. 

Fritz Henglein
DIKU, University of Copenhagen
Existence and uniqueness of induced ordering

**Proposition**

\[ \leq_f \text{ exists and is unique.} \]

Furthermore, \( x \leq_f x' \Leftrightarrow \exists \vec{y} : \vec{y} \in \text{range}(f). \vec{y} = \ldots x \ldots x' \ldots; \]

that is, \( x \leq_f x' \) if and only if \( x \) occurs to the left of \( x' \) in the output of \( f \) for some input \( \vec{x} \).
Every permutation function $f$ induces a unique “best” ordering relation $\leq_f$ consistent with $f$.

When somebody asks: “You have a permutation function and say that it sorts its input. But what is the ordering relation it sorts according to?”

We have an answer: “It is the canonically induced ordering relation, which is uniquely determined by the permutation function.”

So, is every permutation function a function that “sorts”?
Bad news: Undecidability

- Every permutation function $f$ canonically induces an ordering relation $\leq_f$.
- How do we get a handle on it? Can we implement it using $f$?
- Bad news: It is *impossible* to implement $\leq_f$ using $f$!

**Theorem (Undecidability of canonically induced ordering relation)**

There exists a total, computable permutation function $f : \mathbb{N}_0^* \rightarrow \mathbb{N}_0^*$ such that its canonically induced ordering relation $\leq_f$ is recursively undecidable.
Local evidence of the ordering relation

**Definition** \((R_f)\)

Define \(R_f(x_1, x_2) \iff f(x_1x_2) = x_1x_2 \lor f(x_2x_1) = x_1x_2\).

\(R_f(x_1, x_2)\) is “local” evidence for \(x_1 \leq_f x_2\).

**Proposition**

*Let \(f\) be a permutation function. Then \(R_f \subseteq \leq_f\).*
Local consistency

**Definition (Local consistency)**

A permutation function $f : S^* \rightarrow S^*$ is *locally consistent* if $x_1 \leq_f x_2 \implies R_f(x_1, x_2)$ for all $x_1, x_2 \in S$.

**Requirement 2**: $f$ must be locally consistent: $\leq_f \subseteq R_f$. 

**Definition (Relations respecting relations)**

Let $R, R' \subseteq S \times S$ be binary relations. We say $R$ respects $R'$ if $R \subseteq R'$.

**Definition (Preserving relations)**

Function $f : S^* \rightarrow S^*$ preserves relation $R \subseteq S \times S$ if $f(x_1 x_2 \ldots x_n) R^* f(x'_1 x'_2 \ldots x'_n)$ whenever $x_1 x_2 \ldots x_n R^* x'_1 x'_2 \ldots x'_n$. 
A permutation function $f : S^* \rightarrow S^*$ is *parametric* if it preserves all relations that respect $\equiv_f$.

We can now formulate the obliviousness property of sorting algorithms as a parametricity requirement.

**Requirement 3:** $f$ must be parametric.
Lemma (Parametricity implies locality)

Let $f : S^* \rightarrow S^*$ be a parametric permutation function. Then:

1. $f$ is locally consistent: $x_1 \leq_f x_2$ if and only if $R_f(x_1, x_2)$.

2. $x \equiv_f y \iff (f(x_1 x_2) = x_1 x_2 \land f(x_2 x_1) = x_2 x_1) \lor (f(x_1 x_2) = x_2 x_1 \land f(x_2 x_1) = x_1 x_2)$

For all $x, y \in S$. 

Fritz Henglein

DIKU, University of Copenhagen

What is a Sorting Function?
Sorting function: Definition

With local consistency subsumed by parametricity, we define a sorting function to be any parametric permutation function.

Definition (Sorting function)

We call a function \( f : S^* \rightarrow S^* \) a sorting function if

1. (permutativity) it is a permutation function;
2. (parametricity) it preserves all relations that respect the equivalence relation \( Q_f \) defined by

\[
Q_f(x_1, x_2) \iff (f(x_1 x_2) = x_1 x_2 \land f(x_2 x_1) = x_2 x_1) \lor (f(x_1 x_2) = x_2 x_1 \land f(x_2 x_1) = x_1 x_2).
\]
Comparison-based sorting functions

A comparison-based sorting algorithm is an algorithm that is allowed to apply an inequality test (comparison function) to the elements in its input sequence, but has no other operations for operating on the input elements.

Definition (Comparison-based sorting function)

A comparison-based sorting function on $S$ is a function $F : (S \times S \rightarrow \text{Bool}) \rightarrow S^* \rightarrow S^*$ that is

1. (parametricity) $F : \forall X. (X \times X \rightarrow \text{Bool}) \rightarrow X^* \rightarrow X^*$.

2. (sorting) if $lte$ is a comparison function then $F(lte)$ is a permutation function consistent with (the ordering relation corresponding to) $lte$. 
Theorem

Let $F$ be a comparison-based sorting function on $S$. Let $\text{lte} : S \times S \to \text{Bool}$ be a comparison function. Then $f = F(\text{lte})$ is a parametric permutation function and $x_1 \leq_f x_2 \iff \text{lte}(x_1, x_2) = \text{true}$. 
A key-based (distributive) sorting algorithm may operate on totally ordered keys using any operation whatsoever, including bit operations.

**Definition (Key-based (distributive) sorting function)**

A *key-based (distributive) sorting function* on \( S \) is a function \( F : (S \to K) \to S^* \to S^* \) for some total order \((K, \leq_K)\) such that:

1. **(parametricity):** \( F : \forall X.(X \to K) \to X^* \to X^* \).
2. **(sorting):** \( F(key) \) is a permutation function that is consistent with the key order \(((K, \leq_K), key)\).
Theorem

Let $F$ be a key-based sorting function on $S$. Let $((K, \leq_K), \text{key} : S \rightarrow K)$ be a key order. Then $f = F(\text{key})$ is a parametric permutation function and $x_1 \leq f x_2 \iff \text{key}(x_1) \leq_K \text{key}(x_2)$. 
Nonexamples of sorting functions: Wrong type

Recall: “Sorting function” means “parametric permutation function”.

- Consider \( \text{sortBy} : (X \times X \rightarrow \text{Bool}) \rightarrow X^* \rightarrow X^* \) as defined in the Haskell base library. This is a comparison-based sorting function, not a sorting function for the simple reason that it does not have the right type. \( \text{sortBy} \) returns a sorting function when applied to a comparison function.

- Consider a probabilistic or nondeterministic sorting algorithm, such as Quicksort with random selection of the pivot element. It does not implement a sorting function for the simple reason that it is not a \textit{function}: the same input may be mapped to different outputs during different runs.
Consider the permutation function of the Undecidability Theorem. It is not locally consistent and thus not parametric. Ergo it is not a sorting function. Even though it orders the input such that the output respects some ordering relation we cannot use it to decide the ordering relation.
Nonexamples (continued): Not parametric

- Consider the function $f : \mathbb{N}_0^* \rightarrow \mathbb{N}_0^*$ that first lists the even elements in its input and then the odd ones, in either case in the same order as in the input. $f$ is a sorting function. Now modify $f$ as follows:

$$f'(6 \ 8 \ 15) = 8 \ 6 \ 15$$

$$f'(\vec{x}) = f(\vec{x}), \text{otherwise}$$

- $f'$ is locally consistent, but not parametric.
- Intuition: $f'$ inspects “satellite data”.
Definition (Stability)

A permutation function \( f : S^* \rightarrow S^* \) is stable if it preserves the relative order of \( \equiv_f \)-equivalent elements in its input.

We can now add as a requirement on a stable sorting function \( f \) that it be a sorting function and that

**Requirement 4:** \( f \) must be stable.
Lemma (Stability implies parametricity)

Let \( f : S^* \rightarrow S^* \) be a stable permutation function. Then:

1. \( f \) is parametric.
2. \( x \leq_f y \iff f(xy) = xy \)
Stable sorting function

Definition (Stable sorting function)

We call a function $f : S^* \rightarrow S^*$ a stable sorting function if

- (permutativity) it is a permutation function;
- (stability) it is stable.
Permutation functions on total orders

Corollary

Let $f$ be a permutation function consistent with total order $(S, \leq_S)$. Then:

- $f$ is stable.
- $f$ is parametric.
- $f$ is locally consistent.

This means: Sorting on total orders—instead of total preorders—is “uninteresting”.

Fritz Henglein
DIKU, University of Copenhagen
Permutation functions and ordering relations

All permutation functions: many-many. Each permutation function is consistent with many ordering relations, and each ordering relation is consistent with many permutation functions.

Parametric permutation functions: many-one. Each parametric permutation function $f$ is consistent with exactly one ordering relation $R$ such that $f$ is $R$-parametric, and each ordering relation is consistent with many such functions.

Stable permutation functions: one-one. Each stable permutation function $f$ is consistent with exactly one ordering relation $R$ such that $f$ is $R$-stable, and each ordering relation is consistent with exactly one such permutation function.
**Theorem (Local characterization of stability)**

Let $f : S^* \rightarrow S^*$. The following statements are equivalent:

1. $f$ is a stable permutation function.
2. $f$ is consistently permutative: For each sequence $x_1 \ldots x_n \in S^*$ there exists $\pi \in S_{|\bar{x}|}$ such that
   - $f(x_1 \ldots x_n) = x_{\pi(1)} \ldots x_{\pi(n)}$ (permutativity);
   - $\forall i, j \in [1 \ldots n] : f(x_ix_j) = x_ix_j \iff \pi^{-1}(i) \leq_{\omega} \pi^{-1}(j)$ (consistency).

$\pi^{-1}$ maps the index of an element occurrence to its rank. Consistency expresses that the relative order of two elements in the output of $f$ must always be the same.
Noncharacterizations

The interesting part about the characterization is that there are numerous—at least plausible-looking—“noncharacterizations”. (Elided.)
How to provide access to an ordering relation?

Imagine we are interested in providing clients access to an ordered datatype. How should the ordering relation be offered to clients as an operation? Possibilities:

- comparison function
- comparator
- sorting function (or variant such as sorting discriminator)
- ranking function (mapping to particular type with standard ordering)
Isomorphisms

Consider the following classes:

- $\text{TPOrder}^{\text{Set}}$ of orders,
- $\text{Ineq}^{\text{Set}}$ of comparison functions,
- $\text{Comparator}^{\text{Set}}$ of comparators,
- $\text{Sort}^{\text{Set}}$ of stable permutation functions.

Theorem (Order isomorphisms)

*The four classes are isomorphic.*
The isomorphisms mapping between inequality tests, sorting functions and comparators can be defined parametrically polymorphically:

1. $\text{sort}^{\text{lte}} : \forall X. (X \times X \rightarrow \text{Bool}) \rightarrow (X^* \rightarrow X^*)$;
2. $\text{lte}^{\text{sort}} : \forall (\equiv) X. (X^* \rightarrow X^*) \rightarrow (X \times X \rightarrow \text{Bool})$;
3. $\text{sort}^{\text{comp}} : \forall X. (X \times X \rightarrow X \times X) \rightarrow (X^* \rightarrow X^*)$;
4. $\text{comp}^{\text{sort}} : \forall X. (X^* \rightarrow X^*) \rightarrow (X \times X \rightarrow X \times X)$;
5. $\text{comp}^{\text{lte}} : \forall X. (X \times X \rightarrow \text{Bool}) \rightarrow (X \times X \rightarrow X \times X)$;
6. $\text{lte}^{\text{comp}} : \forall (\equiv) X. (X \times X \rightarrow X \times X) \rightarrow (X \times X \rightarrow \text{Bool})$. 

Fritz Henglein
DIKU, University of Copenhagen

What is a Sorting Function?
Representation independence

- Shows that comparison functions, comparators and stable sorting functions are *fully abstract* access functions for observing the ordering relation: They require and reveal nothing else about a type than its ordering relation.

- Comparison functions are definable parametrically from ranking functions \( \text{rank} : T \to \text{Int} \), but not conversely.

- Ranking functions compromise abstraction: There may be client code that uses the ranking function for other purposes than comparing or sorting.
Why fully abstract access matters

- Ranking function *increases* clients’ ability to algorithmically exploit (representation) properties of $T$.
- This *decreases* $T$’s ability to:
  - efficiently implement *other* operations,
  - ensure and exploit representation and interface invariants for correctness and (client and server) efficiency,
  - change and evolve both interface and representation of $T$. 

What is a Sorting Function?
Isomorphism, pictorially

Order as abstract mathematical structure

Isomorphic presentations of Order

What is a Sorting Function?
Isomorphisms are not “structure-preserving”.

What is the “right” structure (notion of morphism) on orders?

Candidates: monotonic (order-preserving) and order-mapping functions

Natural follow-up question: What is the corresponding notion of morphism on sorting structures $\text{Sort}$?

Advance warning: Monotonic functions turn out not to be the “right” notion of structure for $\text{TPOrder}$!
Order-mapping and order-preserving mappings

Definition (Order-preserving, order-mapping)

Let \((S, \leq)\) and \((S', \leq')\) be orders.
We say a function \(g : S \rightarrow S'\) is order-preserving or monotonic if \(x \leq y \implies g(x) \leq' g(y)\) for all \(x, y \in S\).
It is order-mapping if the implication also holds in the converse direction: \(x \leq y \iff g(x) \leq' g(y)\) for all \(x, y \in S\).
Sort-invariant functions

Definition (Sort-invariant function)

Let \((S, \text{sort})\) and \((S', \text{sort}')\) be sorting structures. We say a function \(g : S \rightarrow S'\) is \textit{sort-invariant} if \(g\) commutes with \(\text{sort}\) and \(\text{sort}'\):

\[
\text{Map}\ g(\text{sort}(\vec{x})) = \text{sort}'(\text{Map}\ g(\vec{x})).
\]
Implications

Theorem

Each order-mapping function is sort-invariant (on the induced sorting structure).
Each sort-invariant function is order-preserving (on the induced order).
The converses do not hold, however.

\[
\text{order} \rightarrow \text{mapping} \iff \text{sort} \rightarrow \text{invariant} \iff \text{order} \rightarrow \text{preserving}
\]
Moral summary

■ You can *first* define the notion of “order” and then, by reference to “order”, the notion of “(stable) sorting function”.

■ Have shown that it is possible to *first* define the notion of “(stable) sorting function” and then, by reference to “stable sorting function”, the notion of “order”.

■ The same can be done with the notion of “comparator”.

■ Use intrinsic defining properties to discover when a function *cannot* be a stable sorting function for *any* order.

Challenges

- Exhibit permutation function whose canonically induced ordering relation is undecidable.
- Find notion of morphism on sorting structures corresponding to total preorders with order-mapping functions.
- Figure out which algorithm was used to implement Haskell’s `sortBy` function or any other comparison-parameterized sorting function.
- Passive stable sorting function checking: Observe stream of input-output pairs \((x_1, f(x_1)), \ldots, (x_i, f(x_i)), \ldots\) of a function \(f\). Flag the first index \(i\), if any, where it is clear that \(f\) cannot be a (stable) sorting function.
