## First-Order Logic

James Worrell

First-order logic can be understood as an extension of propositional logic. In propositional logic the atomic formulas have no internal structure - they are propositional variables that are either true or false. In first-order logic the atomic formulas are predicates that assert a relationship among certain elements. Another significant new concept in first-order logic is quantification: the ability to assert that a certain property holds for all elements or that it holds for some element.

## 1 Syntax of First-Order Logic

The syntax of first-order logic is defined relative to a signature. A signature $\sigma$ consists of a set of constant symbols, a set of function symbols and a set of predicate symbols. Each function and predicate symbol has an arity $k>0$. We will often refer to predicates as relations. Typically we use letters $c, d$ to denote constant symbols, $f, g$ to denote function symbols and $P, Q, R$ to denote predicate symbols. Note that the elements of a signature are symbols; only later will will we interpret them as concrete functions or relations. Independent of the signature $\sigma$ we also have an infinite set of variables $x_{0}, x_{1}, x_{2}, \ldots$.

Given a signature $\sigma$, the set of $\sigma$-terms is defined by the following inductive process:

- Each variable is a term.
- Each constant symbol is a term.
- If $t_{1}, \ldots, t_{k}$ are terms and $f$ is a $k$-ary function symbol then $f\left(t_{1}, \ldots, t_{k}\right)$ is a term.

Next the set of formulas is defined inductively as follows:

- Given terms $t_{1}, \ldots, t_{k}$ and a $k$-ary predicate symbol $P$ then $P\left(t_{1}, \ldots, t_{k}\right)$ is a formula.
- For each formula $F, \neg F$ is a formula.
- For each pair of formulas $F, G,(F \vee G)$ and $(F \wedge G)$ are both formulas.
- If $F$ is a formula and $x$ is a variable then $\exists x F$ and $\forall x F$ are both formulas.

Atomic formulas are those constructed according to the first rule above. The atomic formula $P\left(t_{1}, \ldots, t_{k}\right)$ is read " $t_{1}, \ldots, t_{k}$ are in relation $P$ ". The symbol $\exists$ is called the existential quantifier. The formula $\exists x H$ is read "there exists $x, H$ ". The symbol $\forall$ is called the universal quantifier. The formula $\forall x H$ is read "for all $x, H$ ". A general first-order formula is built up from atomic formulas using the Boolean connectives and the two quantifiers. If a formula $F$ occurs as part of another formula $G$ then $F$ is called a subformula of $G$. We assume that the quantifiers bind more tightly than any of the Boolean operators, e.g., $\forall x F \wedge G$ denotes the formula $(\forall x F) \wedge G$.

One important measure of the complexity of a formula $F$ is its quantifier depth, which is denoted $\operatorname{qd}(F)$. We define this by induction on $F$ as follows. Atomic formulas have quantifier depth 0 ; given formulas $F$ and $G, \operatorname{qd}(\neg F)=\operatorname{qd}(F), \operatorname{qd}(F \wedge G)=\operatorname{qd}(F \vee G)=\max (\operatorname{qd}(F), \operatorname{qd}(G))$, and $\operatorname{qd}(\exists x F)=\operatorname{qd}(\forall x F)=\operatorname{qd}(F)+1$.

Example 1. Consider a signature with a single binary relation symbol $R$. Since there are no constant symbols or function symbols, the only terms are variables. An example of a formula is

$$
\forall x \forall y \forall z(R(x, y) \wedge R(y, z) \rightarrow R(x, z)) .
$$

This formula expresses that $R$ is a transitive relation.
Example 2. Consider a signature with a constant symbol 0, unary function symbol $s$, and unary predicate symbol $E$. Terms over this signature include the ground terms (i.e., variable-free terms) $0, s(0), s(s(0)), \ldots$ as well as terms that mention variables, such as $s(x)$. An example of a formula is $E(0) \wedge \forall x(E(x) \leftrightarrow \neg E(s(x)))$.

Sometimes we write function symbols and predicate symbols infix to improve readability:
Example 3. Consider a signature with a constant symbol 1, binary function symbol + , and a binary relation symbol $<$, both written infix. Then $x+1$ is a term and $\forall x(x<(y+1))$ is a formula.

In a formula $\exists x G$ we say that $G$ is the scope of the quantifier $\exists x$. The scope of an occurrence of the universal quantifier is defined similarly. An occurrence of a variable $x$ in a formula $F$ is bound if that occurrence is within the scope of either $\exists x$ or $\forall x$. An occurrence that is not bound is said to be free. Note that the same variable can occur both bound and free in a given formula, e.g., variable $x$ occurs both bound and free in the formula $P(x) \wedge \exists x P(x)$. A formula with no free variables is said to be closed or a sentence. The formulas in Examples 1 and 2 were closed, whereas the formula in Example 3 has a free variable $y$.

We will consider one important variant of first-order logic as described above, namely first-order logic with equality. This variant admits equality as built-in binary relation symbol. Thus, regardless of the signature, we admit $t_{1}=t_{2}$ as an atomic formula for all terms $t_{1}$ and $t_{2}$.

## 2 Semantics of First-Order Logic

Given a signature $\sigma$, a $\sigma$-structure (or assignment) $\mathcal{A}$ consists of:

- a non-empty set $U_{\mathcal{A}}$ called the universe of the structure;
- for each $k$-ary predicate symbol $P$ in $\sigma$, a $k$-ary relation $P_{\mathcal{A}} \subseteq \underbrace{U_{\mathcal{A}} \times \cdots \times U_{\mathcal{A}}}_{k}$;
- for each $k$-ary function symbol symbol $f$ in $\sigma$, a $k$-ary function, $f_{\mathcal{A}}: \underbrace{U_{\mathcal{A}} \times \cdots \times U_{\mathcal{A}}}_{k} \rightarrow U_{\mathcal{A}}$;
- for each constant symbol $c$, an element $c_{\mathcal{A}}$ of $U_{\mathcal{A}}$;
- for each variable $x$ an element $x_{\mathcal{A}}$ of $U_{\mathcal{A}}$.

The above definition treats constant symbols and variables identically. However a key difference is that the interpretation of variables can be overwritten. Given a structure $\mathcal{A}$, variable $x$, and $a \in U_{\mathcal{A}}$, we define the structure $\mathcal{A}_{[x \mapsto a]}$ to be exactly the same as $\mathcal{A}$ except that $x_{\mathcal{A}_{[x \mapsto a]}}=a$.

Often one specifies a structure as a tuple consisting of a set, some relations, some functions and some constants. For example, $(\mathbb{N},<, 0)$ denotes the structure with universe $\mathbb{N}$, binary relation $<$

Figure 1: An undirected graph
(understood as the usual order on $\mathbb{N}$ ) and constant 0 . Note though that this convention does not specify which values are assigned to variables.

We define the value $\mathcal{A} \llbracket t \rrbracket$ of each term $t$ as an element of the universe $U_{\mathcal{A}}$ inductively as follows:

- For a constant symbol $c$ we define $\mathcal{A} \llbracket c \rrbracket \stackrel{\text { def }}{=} c_{\mathcal{A}}$.
- For a variable $x$ we define $\mathcal{A} \llbracket x \rrbracket \stackrel{\text { def }}{=} x_{\mathcal{A}}$.
- For a term $f\left(t_{1}, \ldots, t_{k}\right)$, where $f$ is a $k$-ary function symbol and $t_{1}, \ldots, t_{k}$ are terms, we define $\mathcal{A} \llbracket f\left(t_{1}, \ldots, t_{k}\right) \rrbracket \stackrel{\text { def }}{=} f_{\mathcal{A}}\left(\mathcal{A} \llbracket t_{1} \rrbracket, \ldots, \mathcal{A} \llbracket t_{k} \rrbracket\right)$.

We define the satisfaction relation $\mathcal{A} \models F(\mathcal{A}$ satisfies $F$ or $\mathcal{A}$ models $F)$ between a $\sigma$-structure $\mathcal{A}$ and $\sigma$-formula $F$ by induction over the structure of formulas.

1. $\mathcal{A} \models P\left(t_{1}, \ldots, t_{k}\right)$ if and only if $\left(\mathcal{A} \llbracket t_{1} \rrbracket, \ldots, \mathcal{A} \llbracket t_{k} \rrbracket\right) \in P_{\mathcal{A}}$.
2. $\mathcal{A} \models(F \wedge G)$ if and only if $\mathcal{A} \models F$ and $\mathcal{A} \models G$.
3. $\mathcal{A} \models(F \vee G)$ if and only if $\mathcal{A} \models F$ or $\mathcal{A} \models G$.
4. $\mathcal{A} \models \neg F$ if and only if $\mathcal{A} \not \models F$.
5. $\mathcal{A} \vDash \exists x F$ if and only if there exists $a \in U_{\mathcal{A}}$ such that $\mathcal{A}_{[x \mapsto a]} \models F$.
6. $\mathcal{A} \models \forall x F$ if and only if $\mathcal{A}_{[x \mapsto a]} \models F$ for all $a \in U_{\mathcal{A}}$.

If we are working in first-order logic with equality then we additionally have
7. $\mathcal{A} \models t_{1}=t_{2}$ if and only if $\mathcal{A} \llbracket t_{1} \rrbracket=\mathcal{A} \llbracket t_{2} \rrbracket$.

While the function and predicate symbols in a signature can be interpreted as arbitrary functions and predicates in a given structure, the equality symbol is treated as a "built-in", and is always interpreted as equality.

Example 4. A undirected graph can be considered as a $\sigma$-structure for the signature $\sigma$ with one binary relation symbol $E$, where $E$ is interpreted as the edge relation. For example, the graph shown in Figure 2 can be represented by a structure $\mathcal{A}$ with universe $U_{\mathcal{A}}=\{1,2,3,4\}$ and irreflexive symmetric binary relation

$$
E_{\mathcal{A}}=\{(1,2),(2,3),(3,4),(4,1),(2,1),(3,2),(4,3),(1,4)\} .
$$

Figure 2: Automaton accepting all strings in which each $q$ is followed by some $p$.
The following sentence asserts that edge relation is irreflexive and symmetric:

$$
\forall x \neg E(x, x) \wedge \forall x \forall y(E(x, y) \rightarrow E(y, x))
$$

This sentence is satisfied by the structure in Figure 2,
The following sentence expresses that every pair of nodes are connected by a path of length 3 .

$$
\forall x \forall y \exists z_{1} \exists z_{2}\left(E\left(x, z_{1}\right) \wedge E\left(z_{1}, z_{2}\right) \wedge E\left(z_{2}, y\right)\right) .
$$

This sentence is not satisfied by the structure in Figure 2.
Exercise 5. Let signature $\sigma$ comprise a single unary relation symbol $P$ and let $\mathcal{A}$ be the assignment with $U_{\mathcal{A}}=\{0,1\}$ and $P_{\mathcal{A}}=\{1\}$. Does $\mathcal{A}$ satisfy the sentence

$$
\forall x_{1} \ldots \forall x_{n}\left(P\left(x_{1}\right) \rightarrow\left(P\left(x_{2}\right) \rightarrow\left(P\left(x_{3}\right) \rightarrow \ldots \rightarrow\left(P\left(x_{n}\right) \rightarrow P\left(x_{1}\right)\right) \ldots\right)\right)\right) ?
$$

Have you seen this question before?
Example 6. Consider a signature $\sigma$ with one binary relation symbol <. A totally ordered set satisfies the following sentences in first-order logic with equality:

1. Irreflexivity: $\forall x \neg(x<x)$.
2. Transitivity: $\forall x \forall y \forall z((x<y \wedge y<z) \rightarrow x<z)$.
3. Trichotomy: $\forall x \forall y(x<y \vee y<x \vee x=y)$.

The structures $\left(\mathbb{Z},<_{\mathbb{Z}}\right),\left(\mathbb{Q},<_{\mathbb{Q}}\right)$ and $\left(\mathbb{R},<_{\mathbb{R}}\right)$ all satisfy the above sentences.
Example 7. Let $w=w_{0} w_{1} \ldots w_{n-1}$ be a finite string over an alphabet $\{p, q\}$. Consider a signature $\sigma$ with a binary relation symbol < and unary predicate symbols $P$ and $Q$. We can see $w$ as a $\sigma$ structure $\mathcal{A}$ whose universe $U_{\mathcal{A}}$ is the set $\{0,1, \ldots, n-1\}$ of positions in $w,<_{\mathcal{A}}$ is the usual order on $U_{\mathcal{A}}, P_{\mathcal{A}}=\left\{i: w_{i}=p\right\}$ is the set of positions in which letter $a$ occurs and likewise $Q_{\mathcal{A}}=\left\{i: w_{i}=q\right\}$ is the set of positions in which letter $b$ occurs.

The sentence $F=\forall x(P(x) \rightarrow \exists y(x<y \wedge Q(y)))$ is satisfied by a string precisely when every letter $p$ is followed by a letter $q$. It is easy to see that the set of finite strings that satisfy $F$ is precisely the language of the automaton in Figure 2. In fact for any sentence $F$ over this signature, the set of strings satisfying $F$ defines a regular language.

A first-order formula $F$ over signature $\sigma$ is satisfiable if $\mathcal{A} \models F$ for some $\sigma$-structure $\mathcal{A}$. If $F$ is not satisfiable it is called unsatisfiable. $F$ is called valid if $\mathcal{A} \models F$ for every $\sigma$-structure $\mathcal{A}$. Given a set of formulas $\boldsymbol{S}$ we write $\boldsymbol{S} \models F$ to mean that every $\sigma$-structure $\mathcal{A}$ that satisfies $\boldsymbol{S}$ also satisfies $F$. The same relations exist among these notions as in propositional logic, e.g., $F$ is unsatisfiable if and only if $\neg F$ is valid.

Exercise 8. Consider a signature $\sigma$ with constant symbol 0 , unary function symbol $s$, and unary predicate symbol $P$. Is the $\sigma$-formula $P(0) \wedge \forall x(P(x) \rightarrow P(s(x))) \wedge \exists x \neg P(x)$ satisfiable?

## 3 Reasoning by Induction on Terms and Formulas

Often proofs about first-order logic involve induction on the structure of terms and formulas. We give the following simple lemma by way of example.

Lemma 9 (Relevance Lemma). Suppose that $\mathcal{A}$ and $\mathcal{A}^{\prime}$ are $\sigma$-assignments with the same universe and identical interpretations of the predicate, function, and constant symbols in $\sigma$. If $\mathcal{A}$ and $\mathcal{A}^{\prime}$ give the same interpretation to each variable occurring free in some $\sigma$-formula $F$ then $\mathcal{A} \models F$ if and only if $\mathcal{A}^{\prime}=F$.

Proof. We first show by induction on terms that if $\mathcal{A} \llbracket x \rrbracket=\mathcal{A}^{\prime} \llbracket x \rrbracket$ for each variable $x$ occurring in a given term $t$ then $\mathcal{A} \llbracket t \rrbracket=\mathcal{A}^{\prime} \llbracket t \rrbracket$.

Base cases: If $t$ is either a constant symbol or a variable then $\mathcal{A} \llbracket t \rrbracket=\mathcal{A}^{\prime} \llbracket t \rrbracket$ by assumption.
Induction steps: For $f$ a $k$-ary function symbol we have:

$$
\begin{array}{rlr}
\mathcal{A} \llbracket f\left(t_{1}, \ldots, t_{k}\right) \rrbracket & =f_{\mathcal{A}}\left(\mathcal{A} \llbracket t_{1} \rrbracket, \ldots, \mathcal{A} \llbracket t_{k} \rrbracket\right) \\
& =f_{\mathcal{A}^{\prime}}\left(\mathcal{A} \llbracket t_{1} \rrbracket, \ldots, \mathcal{A} \llbracket t_{k} \rrbracket\right) \\
& \left.=f_{\mathcal{A}^{\prime}}\left(\mathcal{A}^{\prime} \llbracket t_{1} \rrbracket, \ldots, \mathcal{A}^{\prime} \llbracket t_{k} \rrbracket\right) \quad \text { (since } f_{\mathcal{A}}=f_{\mathcal{A}^{\prime}}\right) \\
& =\mathcal{A}^{\prime} \llbracket f\left(t_{1}, \ldots, t_{k}\right) \rrbracket .
\end{array}
$$

We now show by induction on formulas $F$ that if $\mathcal{A}$ and $\mathcal{A}^{\prime}$ agree on the free variables in $F$ then $\mathcal{A} \models F$ if and only if $\mathcal{A}^{\prime} \models F$.

Base cases: Let $F=P\left(t_{1}, \ldots, t_{k}\right)$ be an atomic formula. By assumption, $\mathcal{A} \llbracket x \rrbracket=\mathcal{A}^{\prime} \llbracket x \rrbracket$ for any variable $x$ appearing in some term $t_{i}$. Then

$$
\begin{array}{lll}
\mathcal{A} \models P\left(t_{1}, \ldots, t_{k}\right) & \text { iff } & \left(\mathcal{A} \llbracket t_{1} \rrbracket, \ldots, \mathcal{A} \llbracket t_{k} \rrbracket\right) \in P_{\mathcal{A}} \\
& \text { iff } & \left(\mathcal{A} \llbracket t_{1} \rrbracket, \ldots, \mathcal{A} \llbracket t_{k} \rrbracket\right) \in P_{\mathcal{A}^{\prime}} \quad\left(\text { Since } P_{\mathcal{A}}=P_{\mathcal{A}^{\prime}}\right) \\
& \text { iff }\left(\mathcal{A}^{\prime} \llbracket t_{1} \rrbracket, \ldots, \mathcal{A}^{\prime} \llbracket t_{k} \rrbracket\right) \in P_{\mathcal{A}^{\prime}} \quad \text { (by the above result for terms) } \\
& \text { iff } \mathcal{A}^{\prime} \models P\left(t_{1}, \ldots, t_{k}\right) .
\end{array}
$$

Induction steps: We omit the inductive case for the Boolean connectives. We just give the cases for the universal quantifier (the existential quantifier is similar).

$$
\begin{aligned}
& \mathcal{A} \vDash \forall x F \text { iff } \mathcal{A}_{[x \mapsto a]} \vDash F \text { for all } a \in U_{\mathcal{A}} \\
& \text { iff } \mathcal{A}_{[x \mapsto a]}^{\prime} \models F \text { for all } a \in U_{\mathcal{A}^{\prime}} \quad \text { (induction hypothesis) } \\
& \text { iff } \mathcal{A}^{\prime} \models \forall x F
\end{aligned}
$$

Notice that a variable occurring free in $F$ is either identical to $x$ or it already occurs free in $\forall x F$. Thus $\mathcal{A}_{[x \mapsto a]}$ and $\mathcal{A}_{[x \mapsto a]}^{\prime}$ agree on the free variables of $F$ and we may indeed apply the induction hypothesis above.

A special case of the relevance lemma is that if $F$ is a closed formula and $\mathcal{A}$ and $\mathcal{A}^{\prime}$ are assignments that only differ on the interpretation of variables, then $\mathcal{A} \models F$ if and only if $\mathcal{A}^{\prime} \models F$. For this reason we sometimes don't bother to specify the interpretation of variables when describing assignments in first-order logic.
