## Problem Sheet 1

Instructions: The problem sheets are designed to increase your understanding of the material taught in the lectures, as well as to prepare you for the final exam. You should attempt to solve the problems on your own after reading the lecture notes and other posted material, where applicable. Problems marked with an asterisk are optional. Once you have given sufficient thought to a problem, if you are stuck, you are encouraged to discuss with others in the course and with the lecturer during office hours. You are not permitted to search for solutions online.

## 1 Learning Hyper-rectangles

The concept class of hyper-rectangles over $\mathbb{R}^{n}$ is defined as follows:

$$
C_{n}=\left\{\left[a_{1}, b_{1}\right] \times \cdots \times\left[a_{n}, b_{n}\right] \mid a_{i}, b_{i} \in \mathbb{R}, a_{i}<b_{i}\right\}
$$

Generalise the algorithm discussed in class (for rectangles in $\mathbb{R}^{2}$ ) and show that it efficiently PAC learns the class of hyper-rectangles. Give bounds on the number of samples required to guarantee that the error is at most $\epsilon$ with probability at least $1-\delta$.

Note: You may assume that the distribution $D$ over $\mathbb{R}^{n}$ can be expressed using a continuous density function that is defined over all of $\mathbb{R}^{n}$.

Optional: As an extra challenge, argue why the algorithm still works even when such an assumption regarding the distribution does not hold.

Hint for the Optional Part: For the optional part, we need to change the definition of $C_{n}$ slightly to allow $a_{i} \leq b_{i}$ (rather than $a_{i}<b_{i}$ ). Suppose $R$ is the target hyper-rectangle. Let $p=\mathbb{P}_{\mathbf{x} \sim D}[\mathbf{x} \in R]$. Suppose $p \leq \epsilon$, then the algorithm is always correct. Otherwise, define,

$$
v_{1}=\min \left\{v \geq a_{1} \left\lvert\, \mathbb{P}_{\mathbf{x} \sim D}\left[\left[a_{1}, v\right] \times\left[a_{2}, b_{2}\right] \times \cdots \times\left[a_{n}, b_{n}\right]\right] \geq \frac{\epsilon}{2 n}\right.\right\},
$$

by assumption that $p \geq \epsilon$ the set over which min is taken is non-empty. Argue that the min above is well defined, i.e. using inf is not required, and define $T_{1}$ to be the hyper-rectangle $\left[a_{1}, v_{1}\right] \times\left[a_{2}, b_{2}\right] \times \cdots \times\left[a_{n}, b_{n}\right]$. Similarly, define $T_{2}, T_{3}, \ldots, T_{2 n}$.

Let $T_{1}^{\prime}=\left[a_{1}, v_{1}\right) \times\left[a_{2}, b_{2}\right] \times \cdots \times\left[a_{n}, b_{n}\right]$; notice the open interval for the first dimension. Define $T_{2}^{\prime}, \ldots, T_{2 n}^{\prime}$ analogously. Observe that by definition of $v_{1}$ (requires a careful proof), $\mathbb{P}_{\mathbf{x} \sim D}\left[\mathbf{x} \in T_{i}^{\prime}\right] \leq \frac{\epsilon}{2 n}$ for all $i$. Then observe that if $R^{\prime}$ is the output rectangle produced by the algorithm, then $R \backslash R^{\prime} \subseteq \bigcup_{i=1}^{2 n} T_{i}^{\prime}$.

## 2 PAC Learning : Confidence Parameter

Say that an algorithm $L$ perhaps learns a concept class $C$ using hypothesis class $H$, if for every $n$, for every concept $c \in C_{n}$, for every distribution $D$ over $X_{n}$ and for every $0<\epsilon<1 / 2, L$

# Computational Learning Theory 

Michaelmas Term 2023
given access to $\mathrm{EX}(c, D)$ and inputs $\epsilon$ and size $(c)$, runs in time polynomial in $n$, size $(c)$ and $1 / \epsilon$, and outputs a polynomially evaluatable hypothesis $h \in H_{n}$, that with probability at least 3/4 satisfies $\operatorname{err}(h) \leq \epsilon$. In other words, we've set $\delta=1 / 4$ in the definition of efficient PAC learning. Show that if $C$ is "perhaps learnable" using $H$, then $C$ is also efficiently PAC learnable using $H$.

Hint: You will have to use the Chernoff-Hoeffding bound. Your proof should not rely on $\delta<1 / 2$, in particular it should work for $\delta=3 / 4$, even though we have required $0<\delta<1 / 2$ in the definition of PAC learning.

## 3 Hardness of Learning Boolean Threshold Functions

We will consider the question of learning boolean threshold functions. Let $X_{n}=\{0,1\}^{n}$ and for $\mathbf{w} \in\{0,1\}^{n}$ and $k \in \mathbb{N}, f_{\mathbf{w}, k}: X_{n} \rightarrow\{0,1\}$ is a boolean threshold function defined as follows:

$$
f_{\mathbf{w}, k}(\mathbf{x})= \begin{cases}1 & \text { if } \sum_{i=1}^{n} w_{i} \cdot x_{i} \geq k \\ 0 & \text { otherwise }\end{cases}
$$

Let $\mathrm{TH}_{n}=\left\{f_{\mathbf{w}, k} \mid \mathbf{w} \in\{0,1\}^{n}, 0 \leq k \leq n\right\}$ and $\mathrm{TH}=\bigcup_{n>1} \mathrm{TH}_{n}$. Show that unless RP $=\mathrm{NP}$, there is no efficient PAC-learning algorithm for learning TH, if the output hypothesis is also required to be in TH , i.e., a proper PAC-learning algorithm.

Hint: You should reduce from Zero-One Integer Programming (ZIP) which is known to be NP-complete. An instance of ZIP consists of an $s \times n$ matrix $A$ with entries in $\{0,1\}$, a vector $\mathbf{b} \in\{0,1\}^{s}$ and a pair ( $\mathbf{c}, B$ ) (the objective) with $\mathbf{c} \in\{0,1\}^{n}$ and $B \in \mathbb{Z}$. The decision problem is to determine wither there exists an assignment for the $n$ variables $z_{1}, \ldots, z_{n}$, each variable taking a value in the set $\{0,1\}$, such that for each $1 \leq i \leq s, \sum_{j=1}^{n} A_{i j} z_{j} \leq b_{i}$ and $\sum_{j=1}^{n} c_{j} z_{j} \geq B$.

## 4 Learning Parity Functions

Let $X_{n}=\{0,1\}^{n}$ be the instance space. A parity function, $\chi_{S}$, over $X_{n}$ is defined by some subset $S \subseteq\{1, \ldots, n\}$, and takes the value 1 if an odd number of the input literals in the set $\left\{z_{i} \mid i \in S\right\}$ are 1 and 0 otherwise. For example, if $S=\{1,3,4\}$, then the function $\chi_{S}\left(z_{1}, \ldots, z_{n}\right)=z_{1} \oplus z_{3} \oplus z_{4}$ computes the parity on the subset $\left\{z_{1}, z_{3}, z_{4}\right\}$. Note that any such parity function can be represented by a bit string of length $n$, by indicating which indices are part of $S$. Let PARITIES ${ }_{n}$ denote the concept class consisting of all $2^{n}$ parity functions; observe that the the concept class PARITIES $_{n}$ has representation size at most $n$. Show that the class PARITIES, defined as PARITIES $=\bigcup_{n \geq 1}$ PARITIES $_{n}$, is efficiently proper PAC learnable. You should clearly describe a learning algorithm, analyse its running time and prove its correctness.

Hint: The parity operation can be viewed as addition modulo 2. Use the fact that the set $\{0,1\}$ under addition and multiplication modulo 2 is a field.

## 5 Output Hypothesis as a Turing Machine (*)

Recall that in the definition of efficient PAC-learning, we require that the hypothesis output by the learning algorithm be evaluatable in polynomial time. Suppose we relax this restriction, and let $H$ be the class of all Turing machines (not necessarily polynomial time) - so the output of the learning algorithm can be any program. Let $C_{n}$ be the class of all boolean circuits of size at most $p(n)$ for some fixed polynomial $p$ and having $n$ boolean inputs. Show that $C=\bigcup_{n \geq 1} C_{n}$ is "efficiently" PAC-learnable using $H$ (under this modified definition). Argue that this solution shows that the relaxed definition trivialises the model of learning.

Hint: Outsource the computationally demanding work of finding a consistent classifier to $h$, the hypothesis that makes predictions. Your learning algorithm only needs to indentify what input needs to be given to the Turing Machine $h$.
