6. Classification: Logistic Regression

Varun Kanade

University of Oxford
February 10, 2016

Outline

Today we'll discuss **classification** using **logistic regression**.

- ▶ Discriminative vs Generative Models
- ▶ Likelihood of Logistic Regression
- ▶ Using convex optimization to obtain MLE
- ▶ Logistic Regression in torch

Classification : Generative Models

How are the inputs, tail length and height, distributed given the class?

Model $\Pr(\mathbf{x} \mid y = \text{zebra})$

Model $\Pr(\mathbf{x} \mid y = \text{donkey})$

Example: Model both distributions are multivariate normal with same covariance matrix but different mean

Classification : Generative Models

Discriminative Approach

Don't try to model the inputs $\mathbf{x}$ at all

Model the output y given the input $\mathbf{x}$ and the parameters for the model $\mathbf{w}$

$$y \sim p(\mathbf{x}, \mathbf{w})$$

Discriminative Approach

Don't try to model the inputs $\mathbf{x}$ at all

Model the output y given the input $\mathbf{x}$ and the parameters for the model $\mathbf{w}$

$$y \sim p(\mathbf{x}, \mathbf{w})$$

Pros and cons for both approaches (see Murphy Chapter 8.6)

Focus on discriminative classification

Logistic Regression: Sigmoid Function

The **sigmoid** function, or σ , (a.k.a. **logistic** or **logit**) is defined as

$$\sigma(z) = \frac{e^z}{e^z + 1} = \frac{1}{1 + e^{-z}}$$

Binary Classification: Logistic Regression

As in the case of linear regression, we model y given $\mathbf{x} \in \mathbb{R}^n$ and parameters $\mathbf{w} \in \mathbb{R}^n$

Linear model parametrized by $\mathbf{w} \in \mathbb{R}^n$ composed with **sigmoid** filter

We have,

$$\Pr(y = 1 \mid \mathbf{x}, \mathbf{w}) = \sigma(\mathbf{x}^T \mathbf{w})$$

Binary Classification: Logistic Regression

As in the case of linear regression, we model y given $\mathbf{x} \in \mathbb{R}^n$ and parameters $\mathbf{w} \in \mathbb{R}^n$

Linear model parametrized by $\mathbf{w} \in \mathbb{R}^n$ composed with **sigmoid** filter

We have,

$$\Pr(y = 1 \mid \mathbf{x}, \mathbf{w}) = \sigma(\mathbf{x}^T \mathbf{w})$$

For prediction:

$$\hat{y} = \mathbb{I}(\sigma(\mathbf{x}^T \mathbf{w}) \geq \frac{1}{2})$$

Binary Classification : Logistic Regression

Bernoulli Random Variables

Bernoulli random variable X takes value in $\{0, 1\}$. We parametrize using $\theta \in [0, 1]$.

$$p(1 \mid \theta) = \theta$$

$$p(0 \mid \theta) = 1 - \theta$$

Bernoulli Random Variables

Bernoulli random variable X takes value in $\{0, 1\}$. We parametrize using $\theta \in [0, 1]$.

$$p(1 \mid \theta) = \theta$$

$$p(0 \mid \theta) = 1 - \theta$$

More succinctly, we can write

$$p(x \mid \theta) = \theta^x (1 - \theta)^{1-x}$$

Bernoulli Random Variables

Bernoulli random variable X takes value in $\{0, 1\}$. We parametrize using $\theta \in [0, 1]$.

$$p(1 \mid \theta) = \theta$$

$$p(0 \mid \theta) = 1 - \theta$$

More succinctly, we can write

$$p(x \mid \theta) = \theta^x (1 - \theta)^{1-x}$$

Logistic Regression

y given $\mathbf{x}$ and parameter $\mathbf{w}$ is modelled as Bernoulli variable

$$y \sim \text{Bernoulli}(\sigma(\mathbf{x}^T \mathbf{w}))$$

Likelihood of Logistic Regression

Given data $\mathcal{D} = \langle (\mathbf{x}_i, y_i) \rangle_{i=1}^m$ we can compute the likelihood of observing $\mathbf{y}$ under the logistic regression model

Likelihood of Logistic Regression

Given data $\mathcal{D} = \langle (\mathbf{x}_i, y_i) \rangle_{i=1}^m$ we can compute the likelihood of observing $\mathbf{y}$ under the logistic regression model

$$\begin{aligned} p(\mathbf{y} \mid \mathbf{X}, \mathbf{w}) &= \prod_{i=1}^m \text{Bernoulli}(y_i \mid \sigma(\mathbf{x}_i^T \mathbf{w})) \\ &= \prod_{i=1}^m \left(\frac{1}{1 + e^{-\mathbf{x}_i^T \mathbf{w}}} \right)^{y_i} \left(1 - \frac{1}{1 + e^{-\mathbf{x}_i^T \mathbf{w}}} \right)^{1-y_i} \end{aligned}$$

Likelihood of Logistic Regression

Given data $\mathcal{D} = \langle (\mathbf{x}_i, y_i) \rangle_{i=1}^m$ we can compute the likelihood of observing $\mathbf{y}$ under the logistic regression model

$$\begin{aligned} p(\mathbf{y} \mid \mathbf{X}, \mathbf{w}) &= \prod_{i=1}^m \text{Bernoulli}(y_i \mid \sigma(\mathbf{x}_i^T \mathbf{w})) \\ &= \prod_{i=1}^m \left(\frac{1}{1 + e^{-\mathbf{x}_i^T \mathbf{w}}} \right)^{y_i} \left(1 - \frac{1}{1 + e^{-\mathbf{x}_i^T \mathbf{w}}} \right)^{1-y_i} \end{aligned}$$

Let's look at the negative log likelihood for a single data point $(\mathbf{x}_i, y_i)$

$$\begin{aligned} L(\mathbf{w}; \mathbf{x}_i, y_i) &= -\log(p(y_i \mid \sigma(\mathbf{x}_i^T \mathbf{w}))) \\ &= -(y_i \log(\pi_i) + (1 - y_i) \log(1 - \pi_i)) \end{aligned}$$

Gradient and Hessian of NLL

The negative log likelihood is given by

$$L(\mathbf{w}) = \text{NLL}(\mathbf{y} \mid \mathbf{X}, \mathbf{w}) = - \sum_{i=1}^m (y_i \log(\pi_i) + (1 - y_i) \log(1 - \pi_i))$$

Gradient and Hessian of NLL

The negative log likelihood is given by

$$L(\mathbf{w}) = \text{NLL}(\mathbf{y} \mid \mathbf{X}, \mathbf{w}) = - \sum_{i=1}^m (y_i \log(\pi_i) + (1 - y_i) \log(1 - \pi_i))$$

The gradient and the Hessian (with respect to $\mathbf{w}$) can be computed as:

$$\mathbf{g} = \nabla_{\mathbf{w}} L = \sum_{i=1}^m \mathbf{x}_i (\pi_i - y_i) = \mathbf{X}^T (\boldsymbol{\pi} - \mathbf{y})$$

$$\mathbf{H} = \nabla_{\mathbf{w}}^2 L = \sum_{i=1}^m \pi_i (1 - \pi_i) \mathbf{x}_i \mathbf{x}_i^T = \mathbf{X}^T \text{diag}(\pi_i (1 - \pi_i)) \mathbf{X}$$

Gradient and Hessian of NLL

The negative log likelihood is given by

$$L(\mathbf{w}) = \text{NLL}(\mathbf{y} \mid \mathbf{X}, \mathbf{w}) = - \sum_{i=1}^m (y_i \log(\pi_i) + (1 - y_i) \log(1 - \pi_i))$$

The gradient and the Hessian (with respect to $\mathbf{w}$) can be computed as:

$$\mathbf{g} = \nabla_{\mathbf{w}} L = \sum_{i=1}^m \mathbf{x}_i (\pi_i - y_i) = \mathbf{X}^T (\boldsymbol{\pi} - \mathbf{y})$$

$$\mathbf{H} = \nabla_{\mathbf{w}}^2 L = \sum_{i=1}^m \pi_i (1 - \pi_i) \mathbf{x}_i \mathbf{x}_i^T = \mathbf{X}^T \text{diag}(\pi_i (1 - \pi_i)) \mathbf{X}$$

Homework: Show that $\mathbf{H}$ is positive definite.

NLL is **convex** and has a global minimum

Iteratively Reweighted Least Squares (IRLS)

Apply Newton's method

$$\mathbf{g}_t = \mathbf{X}^T(\boldsymbol{\pi}_t - \mathbf{y}) = -\mathbf{X}^T(\mathbf{y} - \boldsymbol{\pi}_t)$$

$$\mathbf{H}_t = \mathbf{X}^T \mathbf{S}_t \mathbf{X}$$

Iteratively Reweighted Least Squares (IRLS)

Apply Newton's method

$$\begin{aligned}\mathbf{g}_t &= \mathbf{X}^T(\boldsymbol{\pi}_t - \mathbf{y}) = -\mathbf{X}^T(\mathbf{y} - \boldsymbol{\pi}_t) \\ \mathbf{H}_t &= \mathbf{X}^T \mathbf{S}_t \mathbf{X}\end{aligned}$$

Newton's update says:

$$\begin{aligned}\mathbf{w}_{t+1} &= \mathbf{w}_t - \mathbf{H}_t^{-1} \mathbf{g}_t \\ &= \mathbf{w}_t + (\mathbf{X}^T \mathbf{S}_t \mathbf{X})^{-1} \mathbf{X}^T (\mathbf{y} - \boldsymbol{\pi}_t) \\ &= (\mathbf{X}^T \mathbf{S}_t \mathbf{X})^{-1} \mathbf{X}^T (\mathbf{S}_t \mathbf{X} \mathbf{w}_t + \mathbf{y} - \boldsymbol{\pi}_t) = (\mathbf{X}^T \mathbf{S}_t \mathbf{X})^{-1} (\mathbf{X}^T \mathbf{S}_t \mathbf{z}_t)\end{aligned}$$

Iteratively Reweighted Least Squares (IRLS)

Apply Newton's method

$$\begin{aligned}\mathbf{g}_t &= \mathbf{X}^T(\boldsymbol{\pi}_t - \mathbf{y}) = -\mathbf{X}^T(\mathbf{y} - \boldsymbol{\pi}_t) \\ \mathbf{H}_t &= \mathbf{X}^T \mathbf{S}_t \mathbf{X}\end{aligned}$$

Newton's update says:

$$\begin{aligned}\mathbf{w}_{t+1} &= \mathbf{w}_t - \mathbf{H}_t^{-1} \mathbf{g}_t \\ &= \mathbf{w}_t + (\mathbf{X}^T \mathbf{S}_t \mathbf{X})^{-1} \mathbf{X}^T (\mathbf{y} - \boldsymbol{\pi}_t) \\ &= (\mathbf{X}^T \mathbf{S}_t \mathbf{X})^{-1} \mathbf{X}^T (\mathbf{S}_t \mathbf{X} \mathbf{w}_t + \mathbf{y} - \boldsymbol{\pi}_t) = (\mathbf{X}^T \mathbf{S}_t \mathbf{X})^{-1} (\mathbf{X}^t \mathbf{S}_t \mathbf{z}_t)\end{aligned}$$

This is a least square solution for the system

$$\sum_{i=1}^m S_{t,i} (\mathbf{x}_i^T \mathbf{w} - z_{t,i})^2$$

Multi-class, Softmax Formulation, Multinoulli¹

Logistic Regression as a Neural Network

¹Kevin Murphy's usage

Softmax in Torch

`nn.SoftMax()`

Likelihood for multi-class

Classes: $\{1, \dots, C\}$

Indicator function:

$$\mathbb{I}_c(y) = \begin{cases} 1 & \text{if } y = c \\ 0 & \text{otherwise} \end{cases}$$

The parameters $\mathbf{W}$ is now a $n \times C$ matrix

For a single data point $(\mathbf{x}, y)$ the likelihood is:

$$p(y \mid \mathbf{x}, \mathbf{W}) = \prod_{c=1}^C \pi_c^{\mathbb{I}_c(y)}$$

And the negative log likelihood is

$$L(\mathbf{W}; \mathbf{x}, \mathbf{y}) = - \sum_{c=1}^C \mathbb{I}_c(y) \log(\pi_c)$$

Multiclass Logistic Regression in Torch

example-logistic-regression.lua

```
require 'nn'; require 'optim';  
model = nn.Sequential()  
ninputs = 10; noutputs = 3  
model:add(nn.Linear(ninputs, noutputs))  
model:add(nn.LogSoftMax())  
criterion = nn.ClassNLLCriterion()  
-- define some input and target  
-- to evaluate model  
model:forward(input)  
-- to evaluate loss  
criterion:forward(model:forward(input), target)  
-- to compute gradients  
model:backward(input, criterion:backward(model.output, target))
```
